

Third International Conference on Philosophy of Information

**Meaning generation for animals, humans and artificial agents.
An evolutionary perspective on the philosophy of information.**

[Christophe Menant](#) - independent scholar – Bordeaux- France –

- Extended Abstract -

Abstract: Meanings are present everywhere in our environment and within ourselves. But these meanings do not exist by themselves. They are associated to information and have to be created, to be generated by agents. The Meaning Generator System (MGS) has been developed to model meaning generation in agents following a system approach in an evolutionary perspective. The agents can be natural or artificial. The MGS generates meaningful information (a meaning) when it receives information that has a connection with an internal constraint to which the agent is submitted. The generated meaning is to be used by the agent to implement actions aimed at satisfying the constraint. We propose here to highlight some characteristics of the MGS that could be related to items of philosophy of information.

Keywords: information; meaning; constraint; representation; evolution; self-consciousness; anxiety management; philosophy of information; ethics; symbol grounding problem

1. Introduction

Meanings are present everywhere. These meanings are associated to information and have to be generated by agents. We humans manage meanings permanently, consciously or not. We are meaning generating agents. Animals also are (a mouse seeing a cat will generate a meaning: 'danger'). Such a perspective can be extended to Artificial Agents (AAs) where the detection of an obstacle can generate a meaning within a robot programmed to avoid obstacles.

A system approach to meaning generation based on internal constraint satisfaction has been developed in an evolutionary perspective for animals, humans and AAs (the Meaning Generator System) [2]. We look here at positioning the MGS relatively to elements of the philosophy of information. We begin by presenting the MGS as being a system that generates meaningful information when it receives information that has a connection with the constraint. The generated meaning is to be used by the agent containing the MGS for action implementation aimed at constraint satisfaction. We highlight the characteristics of the MGS in order to see how some could be linked to philosophy of information.

Following an evolutionary approach we begin by addressing meaning generation in animal life where agents are submitted to 'stay alive' and 'live group life' constraints. Such simple case can be modeled with a meaning generation structure that brings up the MGS.

The MGS is next extended to humans with challenges related to our limited understanding of human mind where new conscious and unconscious constraints drive the meaning generation processes. To get some understanding of human constraints we use an evolutionary scenario for self-consciousness based on the evolution of meaningful representations.

Meaning generation in AAs is the next step. Constraints in AAs are different from the ones existing in living entities. The latter are intrinsic to the agent but the former are derived from the

human designer of the AA. These derived constraints participate to the generation of derived meaning. Using the MGS for AAs brings up subjects related to the meaning of information in Artificial Intelligence (AI) [4].

Highlighting the characteristics of the MGS for these different usages allows positioning them relatively to some aspects of Philosophy of Information (PI).

2. Meaning generation in animals, humans and artificial agents.

The Meaning Generator System.

The Meaning Generator System is represented in Figure 1. It is part of an agent submitted to an internal constraint. The generated meaning is information leading the agent to implement an action satisfying the constraint in a dynamic mode. The action can be internal or external to the agent, and it can be physical, biological or mental.

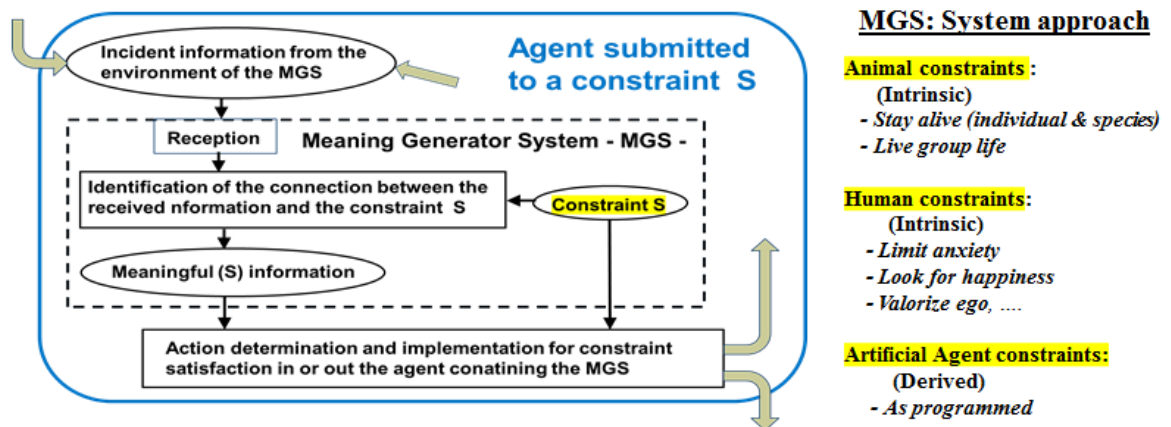

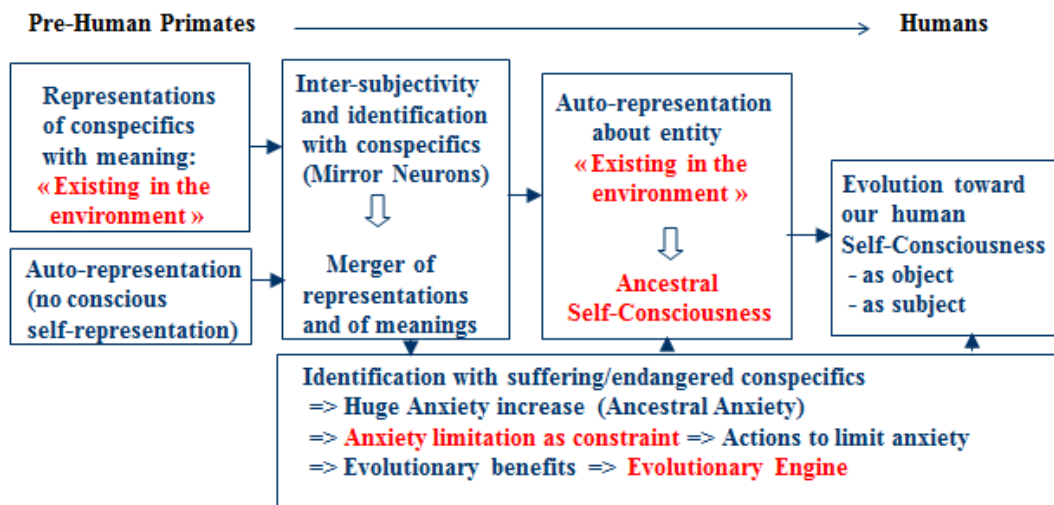

Figure 1. The Meaning Generator System (MGS)

The MGS is usable for basic life: the meaning 'danger' generated when a mouse submitted to a 'stay alive' constraint sees a cat will trigger a hide or run away action to satisfy the constraint. The stay alive constraint applies to individual and to species, and both can be conflicting (ants can get drowned to be a bridge for other ants) [1].

As said, application to humans is more complex as the understanding of human constraints is limited by our lack of visibility on the nature of human mind. To reach some understanding of human constraints we use an evolutionary scenario for self-consciousness that introduces anxiety limitation as a generic human constraint [3]. The scenario is based on the evolution of meaningful representations. It describes what could have been an evolution toward an elementary form of self-consciousness (an 'ancestral self-consciousness') resulting from pre-human primates becoming able to represent their own entities as existing in the environment like conspecifics were represented. Such performance is assumed as having been possible by an evolution of inter-subjectivity into identification with conspecifics at pre-human times. But the identification with conspecifics was also about identifying with suffering or endangered conspecifics that has produced a huge anxiety increase within our ancestors, an 'ancestral anxiety', having the same evolutionary origin that our ancestral self-consciousness. Anxiety limitation processes implemented to limit that anxiety increase have procured key evolutionary advantages and structured an 'evolutionary engine' favoring the evolution toward humans [3]. That evolutionary scenario links the nature of human consciousness to anxiety management.

The evolutionary scenario is summarized in Figure 2.

- * **Evolutionary scenario => Self-consciousness unconsciously interwoven with anxiety management.**
- * **Unconscious anxiety limitation processes as key driver of human minds.**
- Much more than assumed so far.**
- * **Human Constraint: Limit anxiety, Look for happiness, Valorise ego, ...**

As introduced above, using the MGS for Artificial Agents (AAs) brings in constraints of a different type than the natural/intrinsic ones existing in living entities. The internal constraints of AAs come from their designers, they are derived constraints that produce derived meanings. Such characterization of AAs introduces a system approach on the Symbol Grounding Problem (SGP) and to ethical concerns related to AI [4].

3. Philosophy of Information and the MGS

The philosophy of information (PI) is a huge research domain [10]. The focus of PI on information brings to look at possible compatibilities with the MGS approach. Among the many possible items to be compared we propose to look at the following ones:

- Meaningfulness. The MGS considers meaningful and meaningless information. PI deals with semantic information as well formed, meaningful and truthful data [10]
- Meaning generation. The function of meaning generation is at the core of the MGS approach. PI does not prioritize that aspect in semantic information.
- Evolution. The MGS is an evolutionary approach to meaning generation. Current PI does not explicitly consider evolution as an active part of semantic information.
- Veridicality thesis. PI considers that semantic information has to encapsulate truthfulness. The MGS does not use truth as a component of meaningful information.
- Symbol grounding problem. MGS and PI both address the SGP but they reach different conclusions [4, 6, 8]
- Ontological status of information. PI addresses that question in terms of ontological category. MGS proposes an option with potential local constraints in a pre-biotic world [5].
- Naturalization of meaning. PI addresses this subject under various perspectives. MGS proposes an answer based on internal constraint satisfaction [1].

Some of these relations have been already addressed by other authors following different perspectives [7, .9].

The above list is far from being exhaustive as other information related items could be taken into account. More work is needed on this subject.
